A research group led by Dr. Keisuke Kataoka at National Cancer Center (President, Dr. Hitoshi Nakagama, Tokyo, Japan), through joint research with Professor Yasushi Okuno of Kyoto University and Professor Satoru Miyano of The Institute of Medical Science, The University Of Tokyo, has completed a comprehensive genomic study of more than 60,000 cancer samples, discovering that multiple mutations within individual oncogenes (hereafter MMs) synergistically promote cancer progression. The results of this research were published on the online edition of the British journal *Nature* on April 8 (GMT), 2020.

The findings of this study are summarized as follows (Fig. 1):

(1) It had long been believed that oncogenes gain tumor-promoting functions by acquiring single mutations each individually, but the research team has discovered that MMs are commonly observed in several oncogenes. They were particularly prominent in *PIK3CA* and *EGFR* genes, in which 10% of the mutated samples carried MMs respectively. Most of these MMs were located on the same side of the chromosome (*in cis*).

(2) Minor (infrequent) mutations were preferentially selected in MMs. Individually, these minor mutations were functionally weak, but synergistically, they exhibited stronger oncogenic potential.

(3) Samples with *PIK3CA* MMs showed enhanced downstream pathway activation and higher dependency on the mutated gene itself. They also showed higher sensitivity to specific inhibitors.

The results of this study show that MMs within individual oncogenes serve as a novel genetic mechanism in cancer pathogenesis, also providing an explanation as to why functionally weak minor mutations are accumulated in cancer. In addition, MMs in oncogenes can be exploited as a biomarker for predicting benefits of molecular targeted therapies. Therefore, the application of our findings in cancer precision medicine is anticipated.
